- Office Hours: Saturdays 1:00pm - 2:30pm EST

Section 4: JavaScript

Agenda

- JavaScript
 - Declarations
 - Comments
 - Functions
 - DOM Manipulation
 - Event Handling
- Problem Set 3 Instructions & Hints

JavaScript

JavaScript is a lightweight, interpreted, object-oriented language, and it is best known as the scripting language for Web pages.

Recommended for JavaScript practice: <https://jsfiddle.net/>

Declarations

JavaScript has three kinds of variable declarations.

- **var**: Declares a function scope variable
- **let**: Declares a block-scoped, local variable
- **const**: Declares a block-scoped, read-only named constant

Comparison Table

	var	let	const
reassigned	O	O	X
Scope	Function Scope	Block Scope	Block Scope
Reference before declaration	O	X	X

Declarations

The use of **let** is recommended over **var**, because redeclaring a variable using the **var** keyword can impose problems.

For example, redeclaring a variable inside a block will also redeclare the variable outside the block:

```
var x = 5;  
{  
  var x = 10;  
}  
// x is 10
```

```
let x = 5;  
{  
  let x = 10;  
}  
// x is 5
```

Comments

Single line comments start with `//`.

```
// a single line comment
```

Multi-line comments start with `/*` and end with `*/`.

```
/* a multi-line comment */
```

Functions

A JavaScript function is defined with the function keyword, followed by a name, followed by parentheses ().

```
function myFunction(parameter1, parameter2) {  
    return parameter1 * parameter2  
}
```

HTML ▼

```
1 <p id="demo"></p>
```

CSS ▼

```
1
```

JavaScript + No-Library (pure JS) ▼

≡ Tidy

```
1 ▼ function myFunction(parameter1, parameter2) {  
2     return parameter1 * parameter2  
3 }  
4  
5 document.getElementById("demo").innerHTML = myFunction(10, 2);
```

20

Functions

A JavaScript function can be anonymous:

```
const square = function(p1) {  
    return p1*p1  
}
```

HTML ▼

```
1 <p id="demo"></p>
```

CSS ▼

```
1
```

JavaScript + No-Library (pure JS) ▼

≡ Tidy

```
1  
2 ▼ const square = function(p1) {  
3     return p1 * p1  
4 }  
5  
6 document.getElementById("demo").innerHTML = square(10);
```

100

Functions

A JavaScript function can be used as a variable.

```
let text = "The temperature is " + Celsius(68) + " Celsius";
```

HTML ▼

```
1 <p id="demo"></p>
```

CSS ▼

```
1
```

JavaScript + No-Library (pure JS) ▼

≡ Tidy

```
1 let demo = document.getElementById("demo");
2
3 demo.innerHTML = "The temperature is " + Celsius(68) + " Celsius";
4
5 function Celsius(fahrenheit) {
6   return (5/9) * (fahrenheit-32);
7 }
8
```

The temperature is 20 Celsius

Functions

A JavaScript function can be self invoked. You have to add parentheses around the function to indicate that it is a function expression.

```
(function () {  
    demo.innerHTML = "Hello! I called myself";  
})();
```

HTML ▼

```
1 <p id="demo"></p>
```

CSS ▼

```
1
```

JavaScript + No-Library (pure JS) ▼

≡ Tidy

```
1 let demo = document.getElementById("demo");  
2  
3 ▼ (function () {  
4     demo.innerHTML = "Hello! I called myself";  
5 })();
```

Hello! I called myself

DOM (Document Object Model) Manipulation

Method:

The most common way to access an HTML element is to use the id of that element.

In my previous examples the `getElementById` method used `id="demo"` to find the appropriate HTML element.

Property:

To get the content of an element use the `innerHTML` property.

The `innerHTML` property can be used to get or change/replace any HTML element.

DOM (Document Object Model) Manipulation

Other methods to get HTML elements:

- `document.getElementsByTagName("p");`
- `document.getElementsByClassName("myClass");`
- `document.querySelectorAll("p.myClass");`

Other properties:

- `.Attribute`: the attribute value of an HTML element
- `.style.Property`: the style property of an HTML element

Event Handling

Events

A script (JavaScript) can be executed when an HTML event occurs.

HTML event examples:

- When a user clicks the mouse
- When the mouse hovers over an element
- When an input field is changed
- When an HTML form is submitted
- A web page was loaded

Event Handling

Event Listener Method

The `addEventListener()` method attaches an event handler to the specified element. It takes two arguments: the event and the function.

Examples:

- `document.getElementById("myButton").addEventListener("click", myFunction);`
- `element.addEventListener("mouseover", mySecondFunction);`
- `element.addEventListener("mouseout", myThirdFunction);`

Project 3

Mail

- Download the project zip folder and unzip it
- Move the project to a location that you have easy access through your terminal
- Once you open the folder you will find two subfolders, `mail`, `project3`, and a `manage.py` file
- Run `python(3) manage.py makemigrations mail` to make migrations for the mail app.
- Run `python(3) manage.py migrate` to apply migrations to your database.

Project 3

Next steps:

1. Check your templates

- inbox.html: need to add a division for viewing emails.
 - From, To, Subject, Timestamp, Body
 - Buttons: Reply, Archive, Unarchive

Project 3

Next steps:

2. Check Static

- styles.css: it is recommended that you to add some style
- inbox.js: your JavaScript code goes here

Project 3

inbox.js - what is needed:

- Anonymous function:
 - When form is submitted, send a new email
 - Allow user to mark an email as archived or unarchived
 - Handle when user replies to an email
- load_mailbox function:
 - You need to add a query for the latest emails
 - You will find the fetch() method useful here. Remember the syntax:
`fetch(`...`).then(response => response.json()).then(emails => {...});`

Project 3

inbox.js - what is needed:

- New Functions
 - Add email(s) to the mailbox
 - Archive an email
 - Reply to an email
 - Send an email

Q&A
